What is hepatitis C?

Hepatitis C is a virus that attacks the liver, an organ that performs many important functions for the body. The liver is essential to good health.

If left untreated, hepatitis C injures the liver over time. This can lead to serious health problems such as liver failure, liver cancer and early death. **However, hepatitis C can be cured.**

How does someone get hepatitis C and how can this be prevented?

Hepatitis C is passed when blood from a person with hepatitis C gets into the blood of someone without hepatitis C.

In Canada, hepatitis C is commonly passed through sharing drug use equipment, especially injection drug use equipment.

Hepatitis C can also be passed:

- through reusing unsterilized tattooing or body piercing equipment
- from a pregnant parent to a child during pregnancy or childbirth
- during sex (while the risk is very low, it is possible; this is more common among men who have sex with men)
- through sharing personal care items like razors, nail clippers and toothbrushes

Hepatitis C can no longer be passed through donated blood or tissue in Canada. Canada started testing donated blood and tissue for hepatitis C in 1992.

Hepatitis C is never passed by hugging, kissing or touching someone who has the

can also be passed through close contact with someone who has hepatitis A. Most people who get hepatitis A recover from it on their own. When this happens, they are immune to the virus and cannot get hepatitis A again.

Hepatitis B can be passed from one person to another through blood, semen or vaginal fluid. Hepatitis B can also be passed to a baby during childbirth. Most people who get hepatitis B recover on their own; after this, they cannot get hepatitis B again. However, some people with hepatitis B develop a chronic hepatitis B infection. This is more common in people who get hepatitis B when young. Chronic hepatitis B can lead to long-term liver problems. There is no cure for hepatitis B.

Vaccination is the best way to prevent both hepatitis A and hepatitis B.
