Hello and welcome. Open the door and come in, there is a lot of room, we are happy you have arrived here. Love, support, caring for each other, and helping one another are all very good things. The Métis or half breeds used to help each other a lot when they lived together. They hunted together, they had fun together, and they had a good life.

We know that today there are many sexually transmitted infections out there, and healthcare providers are learning more. They call these HIV, hepatitis C, and Syphilis.

Today these are not as dangerous as they were in the past, and there are medications to help you get well. We all have to work together. Our fellow people need to know this all and we have to help all those affected.

Introduction

- Syphilis is a sexually transmitted infection (STI). Untreated syphilis can lead to serious health problems. The good news is that syphilis can be cured with antibiotics.
- Syphilis is usually passed during sexual contact, including oral, vaginal and anal sex.
- Syphilis can also be passed from a pregnant person to a child during pregnancy or childbirth.
- There are ways to prevent getting or passing syphilis.
- The only way to know if you have syphilis is to get tested.

Read on for answers to common questions about syphilis.

Many people with syphilis do not notice any symptoms. Soon after a person gets syphilis, a small, painless sore may appear on, in or around the site of first exposure (penis, vagina, rectum or mouth). If the infection is left untreated, other symptoms may occur like rashes, headaches and hair loss but these usually disappear within the first few months.</p> <p>Importantly, untreated syphilis stays in the body and can eventually damage the nervous system and organs, leading to serious health problems and potentially becoming life-threatening.</p> <p>Syphilis can be cured with antibiotics. This prevents further damage and stops syphilis from being passed to others.</p>
